# Normal Coordinate Analysis and Spectral Analysis of Cyclohexanone Oxime 

P. MAni*, S. Suresh $\dagger$ and C. Revathi $\ddagger$<br>Department of Physics, Hindustan University, Padur-603 103, India<br>E-mail: mani_hce@yahoo.co.in.

#### Abstract

FTIR and FTR spectra of cyclohexanone oxime have been recorded in the regions 4000-200 and 4000-30 $\mathrm{cm}^{-1}$, respectively. The vibrational analysis has been carried out by assuming $\mathrm{C}_{\mathrm{s}}$ symmetry. The observed frequencies were assigned to various modes of vibrations on the basis of intensity, frequencies from allied molecules and normal coordinate calculations. The potential energy distribution associated with normal modes are also reported here. The assignments of fundamental vibrational frequencies for cyclohexanone oxime agree with the calculated frequencies. The different chemical environments of the protons were ascertained using ${ }^{1} \mathrm{H}$ NMR spectra and the purity of the compound was confirmed by mass spectral data.

Key Words: Vibrational spectra, Normal coordinate calculation, Cyclohexanone oxime.

## INTRODUCTION

Cyclohexanone oxime, a derivative of cyclohexanone is a white crystalline solid that can be crystallized as prisms from hydrocarbon solvents with melting point $90.5^{\circ} \mathrm{C}$ and boiling point $204^{\circ} \mathrm{C}$, sublimes at room temperature. This chemical compound is stable under normal laboratory conditions and the most important commercial derivative of cyclohexanone. Cyclohexanone oxime is an intermediate in the preparation of caprolactam, which is used in nylon manufacture. It is also used as a therapeutic agent. NMR spectra of some oximes were measured at natural isotopic abundance in pyridine and acetonitrile solutions ${ }^{1}$. The temperature dependence of the FT-IR spectra of absorbed cyclohexanone oxime was studied on pentasil zeolite ${ }^{2}$. Thermodynamic properties like heat of crystalline capacities and liquid cyclohexanone oxime were measured by vacuum adiabatic calorimetry ( $6-300 \mathrm{~K}$ ) and by the triple heat bridge method $(300-450 \mathrm{~K})^{3}$. The rearrangement of cyclohexanone oxime to e-caprolactam was investigated over heterogeneous catalysts ${ }^{4}$. Jain et al. ${ }^{5}$ reported the mechanism of reaction of impurities such as cyclohexanol, cyclohexanone, aniline and cyclohexanone oxime, during the course of polymerisation of caprolactam. This indicates that cyclohexanone oxime's application in the manufacture of nylon. A simplified industrial route for the synthesis of cyclohexanone oxime an

[^0]intermediate in the caprolactam process was described by Roffia et al. ${ }^{6}$. This chemical compound was employed as an oxidant in redox polymerization ${ }^{7}$. Talukdar et al. ${ }^{8}$ reported the use of solar energy for the photonitrosation of cyclohexanone for the production of cyclohexanone oxime hydrochloride, an intermediate for the manufacture of caprolactam. In the present work, the spectral analysis of cyclohexanone oxime has been reported. The aim of this work is to propose assign all the vibrational frequencies for cyclohexanone oxime using the normal coordinate analysis through FT-infrared and FT-Raman spectroscopy.

## EXPERIMENTAL

FTIR spectrum of cyclohexanone oxime was recorded on Bruker IFS 66V FTIR spectrophotometer in the region $4000-200 \mathrm{~cm}^{-1}$. FT Raman spectrum of the same compound was also recorded on the same instrument with FRA 106 Raman module equipped with Nd: YAG laser source operating at $1.06 \mu \mathrm{~m}$ line with a scanning speed of $30 \mathrm{~cm}^{-1} \mathrm{~min}^{-1}$ of spectral width $20 \mathrm{~cm}^{-1}$. The frequencies for all sharp bands were accurate to $\pm 1 \mathrm{~cm}^{-1}$. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of cyclohexanone oxime were recorded using Jeol 500 MHz .

Mass spectral analysis: The mass spectra showed a parent molecular ion peak at $\mathrm{m} / \mathrm{z}=113.0(\mathrm{M}+1$ peak $)$, which losses oxime -OH and produces a peak at $\mathrm{m} / \mathrm{z}$ $=96(\mathrm{M}+1$ peak). Next the ring broke down into acetonitrile and $n$-butane in turn confirmed by the peaks at $\mathrm{m} / \mathrm{z}=41(100 \%$, base peak) and $\mathrm{m} / \mathrm{z}=56$, respectively. The $n$-butane group further decomposes to ethyl radical which appeared at $\mathrm{m} / \mathrm{z}=27$.

Theoretical considerations: The molecular symmetry of the molecule helps to determine and classify the actual number of fundamental vibrations of the system. The observed spectrum is explained on the basis of $\mathrm{C}_{\mathrm{s}}$ point group symmetry. The 51 optically active fundamental vibrations are distributed as $\Gamma_{\mathrm{vib}}=35 \mathrm{a}^{\prime}$ (in-plane) $+16 \mathrm{a}^{\prime \prime}$ (out-of-plane).

All the modes are active in both Raman and infrared. The assignments have been made on the basis of relative intensities, magnitudes of the frequencies and polarization of the Raman lines. The vibrational assignment was made in terms of the potential energy distribution, which was obtained from the evaluated constants.

Normal coordinate analysis: The normal coordinate calculations have been performed to obtain vibrational frequencies and the potential energy distribution for the various modes. In the normal coordinate analysis, the potential energy distribution plays an important role for the characterization of the relative contributions from each internal coordinates to the total potential energy associated with particular normal coordinate of the molecule.

The normal coordinate analysis is necessary for complete assignment of the vibrational frequencies of larger polyatomic molecules and for quantitative description of the vibrations. The values of bond-length and bond-angles have been taken from allied molecules and Sutton table ${ }^{9}$. Internal co-ordinates for the out-of-plane torsional vibrations are defined as recommended by IUPAC. The simple valence
force field has been adopted for both in-plane and out-of-plane vibrations. The normal coordinate calculations have been performed using the program of Fuhrer et al. ${ }^{10}$. The initial set of force constants have been taken from the related molecules.

Potential energy distribution: To check whether the chosen set of assignments contribute maximum to the potential energy associated with normal coordinates of the molecules, the potential energy distribution (PED) has been calculated using the relation

$$
\begin{equation*}
\mathrm{PED}=\frac{\mathrm{F}_{\mathrm{ii}} \mathrm{~L}_{\mathrm{ik}}^{2}}{\lambda_{\mathrm{k}}} \tag{1}
\end{equation*}
$$

where $\mathrm{F}_{\mathrm{ii}}$ are the force constants defined by damped least square technique, $\mathrm{L}_{\mathrm{ik}}$ is the normalized amplitude of the associated element ( $\mathrm{i}, \mathrm{k}$ ) and $\lambda_{\mathrm{k}}$ the eigen value corresponding to the vibrational frequency of the element k . The PED contribution corresponding to each of the observed frequencies over $10 \%$ are alone listed in the present work.

## RESULTS AND DISCUSSION

The observed frequencies along with their relative intensities of cyclohexanone oxime and probable assignments are presented in Table-1.

TABLE-1
OBSERVED, CALCULATED FREQUENCIES $\left(\mathrm{cm}^{-1}\right)$, VIBRATIONAL ASSIGNMENTS AND POTENTIAL ENERGY DISTRIBUTION OF CYCLOHEXANONE OXIME

C-H Stretching: In large numbered rings such as cyclohexane, the C-H stretching absorptions are usually observed below $3000 \mathrm{~cm}^{-1}$. In the present case, the absorption band observed at 2977, 2925, 2889 and $2843 \mathrm{~cm}^{-1}$ in the IR spectrum and 2988, $2962,2938,2900,2857$ and $2831 \mathrm{~cm}^{-1}$ in the Raman spectrum are assigned to the C-H stretching present in the cyclohexane ring. The weak and strong wave numbers correspond to symmetric and antisymmetric vibrations of the $\mathrm{C}-\mathrm{H}$ bond. The calculated wave numbers agree with the observed frequencies. The present conclusion is in
agreement with the literature values ${ }^{11-13}$. The PED calculation for C-H stretching indicates that all are pure modes except at the calculated frequency at 2890 and $2849 \mathrm{~cm}^{-1}$ which are mixed modes with little contributions due to $\mathrm{C}-\mathrm{C}$ stretching.

O-H Stretching: In the infrared, O-H stretching band is of medium to strong intensity although it may be broad. However, in Raman spectra, the band is generally weak. The O-H stretching of the cyclohexanone oxime is assigned to $3187 \mathrm{~cm}^{-1}$ which agrees with the calculated frequency ${ }^{14-16}$ at $3181 \mathrm{~cm}^{-1}$.
$\mathbf{C}=\mathbf{N}$ Stretching: For oximes, $\mathrm{C}=\mathrm{N}$ stretching band occurs in the region 1690$1620 \mathrm{~cm}^{-1}$. In the present case, it is assigned to strong infrared at $1669 \mathrm{~cm}^{-1}$ which agrees with calculated frequency at $1664 \mathrm{~cm}^{-1}$ and literature value ${ }^{17}$.

C-C Stretching: The skeletal vibration of alkane is often weak in infrared and usually of weak to medium intensity in Raman spectra. The C-C stretching absorptions occur in the region 1260-700 $\mathrm{cm}^{-1}$. Thus bands observed at $1225,1214,1138,1110$, 1095 and $1088 \mathrm{~cm}^{-1}$ are assigned to six C-C stretching vibrations and they are in good agreement with the calculated frequencies.

## In-plane and out-of-plane bendings

C-H Bending: The $\mathrm{C}-\mathrm{H}$ in plane bending vibration in cyclohexane rings is usually observed in the region between $1400-1000 \mathrm{~cm}^{-1}$ which is normally weak while the C-H out of plane vibrations occurring between $1000-700 \mathrm{~cm}^{-1}$ is normally strong. With this observation, the bands at 1480, 1458, 1436, 1350, 1339, 1331, $1319,1264,1250$ and $1239 \mathrm{~cm}^{-1}$ are assigned to C-H in plane bending while the bands observed at $950,931,919,900,868,850,838,794,656$ and $482 \mathrm{~cm}^{-1}$ are assigned to $\mathrm{C}-\mathrm{H}$ out of plane bending vibrations. These bending vibrations due to the C-H bond well agree with the calculated frequencies as shown in Table-1 and with the literature values ${ }^{18,19}$.

Ring breathing: The $\mathrm{C}-\mathrm{C}-\mathrm{C}$ trigonal bending and $\mathrm{C}-\mathrm{C}-\mathrm{C}$ ring breathing vibrations are assigned to 1019 and $995 \mathrm{~cm}^{-1}$, respectively which agree with calculated values at 1011 and $992 \mathrm{~cm}^{-1}$. This conclusion is in good agreement with the literature values ${ }^{20}$.
${ }^{1} H$ NMR analysis: ${ }^{1} H$ NMR spectra of the compound consists of multiplets in the range $1-3 \mathrm{ppm}$, shows that the ring protons are not equal. Since the protons on $\{B\}$ carbon are cis to oxime - OH they appeared at $\delta=2.50 \mathrm{ppm}$ down field (diamagnetic shift) where as the trans protons on $\{\mathrm{C}\}$ carbon resonates at $\delta=2.22 \mathrm{ppm}$. The rest 6 proton of $\{\mathrm{D}\}$ carbon resonates at $\delta=1.74 \mathrm{ppm}$ (paramagnetic shift). All the three signals were splitted into triplets by the neighbouring two protons. The - OH proton appeared as a board signal at $\delta=8.9 \mathrm{ppm}$.

Structure of cyclohexanone oxime

Similar trend was observed with ${ }^{13} \mathrm{C}$ NMR also. Except carbon all other carbons appeared in the range between $20-40 \mathrm{ppm}$. Due to electron withdrawing nature of N carbon (A) resonators at down field i.e. at $\delta=160 \mathrm{ppm}$.

## Conclusion

A complete vibrational band assignment of cyclohexanone oxime has been carried out using infrared and Raman spectra on the basis of $\mathrm{C}_{\mathrm{s}}$ point group symmetry. The PED calculation regarding the normal modes of vibration provide a strong support for the frequency assignment on the highly complex molecule. A satisfactory spectral analysis has been made for the cyclohexanone oxime using NMR and mass spectra. An NMR spectrum shows that the ring protons are not equal. Mass spectra shows that the molecular mass peak of the compound.
