Acoustic Behaviour of Dysprosium Soaps in Methanol

S.K. UPADHYAY, R.K. SHUKLA and GOVIND SHARMA* Department of Chemistry, Faculty of Engineering & Technology R.B.S. College, Bichpuri Campus, Agra-283 105, India Tel: (91)(562)2636675; (91)9411627153 (M) E-mail: sanjay_upadhllj@rediffmail.com

The studies of ultrasonic velocity in solutions of dysprosium butyrate and velerate soaps in methanol have been used to evaluate the various acoustic parameters. The result shows that ultrasonic velocity, molar sound velocity, density and specific acoustic impedence increases but adiabatic compressibility and intermolecular free length decreases with increasing soap concentration. The values of solvation number are almost constant for dilute solution but decreases rapidly above the critical micelle concentration (CMC) with increasing soap concentration. The apparent molal compressibility and apparent molal volume of dysprosium soap solution in methanol vary linearly below the CMC.

Key Words: Ultrasonic velocity, Adiabatic compressibility, Intermolecular free length, Specific acoustic impedence, Solvation number.

INTRODUCTION

The complimentary use of apparent molal compressibility and adiabatic compressibility data can provide interesting information an ion-solvent interaction and the structure of the solution. Several workers¹⁻⁹ have used ultrasonic velocity measurements for the determination of ion-solvent interaction and the solvation numbers obtained by this technique were found to be in agreement with those computed by other techniques.

EXPERIMENTAL

All chemicals used were of BDH/AR grade, Dysprosium soaps were prepared by direct metathesis as described earlier¹⁰. The solutions were prepared by dissolving known weight of the soap in methanol and were kept for 2 h in a thermostat at $40 \pm 0.05^{\circ}$ C and then used for velocity measurements. The ultrasonic velocity of the soap solutions was measured with a multi-frequency ultrasonic interferometer (Mittal Enterprises, New Delhi) at a frequency of 1 MHz at constant temperature. 2994 Upadhyay et al.

RESULTS AND DISCUSSION

The ultrasonic velocity of dysprosium solutions in methanol at different concentration are given in Fig. 1.

Fig. 1. Ultrasonic velocity vs. concentration of dysprosium soaps in methanol

For any homogeneous dissipative fluid system, the ultrasonic velocity (v) of a compressional acoustic wave is related to the density (ρ) and adiabatic compressibility (β) by the relationship

 $v = (\rho\beta)^{-1/2}$

Adiabatic compressibility is calculated for solutions of dysprosium soap solutions of different concentrations from ultrasonic velocity values and presented in Tables 1 and 2.

The results indicate that the density increases but adiabatic compressibility decreases with soap concentration. These soaps behave as weak electrolytes and ionize. The ions in solution are surrounded by a layer of oriented solvent molecule firmly bound. The increase in internal pressure results in lowering of the compressibility of the soap solution. This explains the lowering of compressibility of the soap solution. This explains the decease in β with concentration.

The decrease in the intermolecular free length ($L_f = k\beta^{1/2}$) is due to the decrease in the compressibility with increasing soap concentration (Tables 1 and 2). The plots of intermolecular free length *vs.* soap concentration which corresponds to CMC of the soap (Fig. 2).

Acoustic Behaviour of Dysprosium Soaps in Methanol 2995

Fig.2 Intermolecular free length vs. concentration of dysprosium soaps in methanol

The plots of specific acoustic impedance vs soap concentration (Fig.3) show break at a definite soap concentration which corresponds to the CMC of the soap.

Vol. 19, No. 4 (2007) Acoustic Behaviour of Dysprosium Soaps in Methanol 2997

The increase in the values of specific acoustic impedance, z, with the soap concentration, c, may be due to interaction between the soap and solvent molecules which increases with intermolecular distance making relatively wider gaps between the molecules and becoming the main cause of impediment in propagation of ultrasonic waves.

The apparent molal properties are found to be dependent on the concentration of the solutions. The apparent molal compressibility ϕ_k can be expressed as:

 $\phi_{k} = 1000/c\rho (\rho_{0}\beta - \beta_{0}\rho) + \mu\beta_{0}/\rho_{0}$

where M is the molecular weight of the soap. The value of ϕ_k increase with increasing soap concentration and also the molecular weight of the soap molecule.

The adiabatic compressibility data have been used to determine the solvation number of the soap by assuming that the ions and the solvent molecules in immediate contact are compressible. This is because the ions add some electrosatatic stiffing on the adjacent solvent molecules which is considered to be equivalent to a large internal pressure on these molecules. Pasynkic¹¹ defined the solvent number S_n and the number of solvent molecules present in the primary solvent sheath and is given by the relationship.

 $S_n = (n_1/n_2) (1 - V\beta/n_1V_0\beta_0)$

where V is the volume of solution containing n_2 moles of solute and V_0 is the molar volume of the solvent. The results show that the solvation number decreases with increasing concentration and increases with the molecular weight of the soap. The higher values of the solvation number are in agreement with the results reported by Padmini and Rao¹² for cobalt acetate.

The plots of ultrasonic velocity *vs* concentration (Fig. 1) shows that it consists of two straight lines intersecting at a point. The slope of this is positive, in agreement with the behaviour reported for electrolytic compounds^{13,14}.

The values of molar sound velocity, R increase linearly with increasing soap concentration and chain length of soap molecules (Tables 1 and 2).

The linear part in lower concentration range represents normal solution of the soap; the point of intersection represents CMC. The value of CMC decreases with the molecular weight of the soaps (Table-3). The linear increase in V with C can be represented by the equation¹⁵.

 $(V-V_0) = GC$

where G is the Garney's constant. The value of G has been calculated from the slope of the linear graph (Fig. 1) and found to increase with the molecular weight of the soap (Table-3).

TABLE-3 CMC AND VARIOUS OTHER ACOUSTIC CONSTANT OF DYSPROSIUM SOAPS IN METHANOL AT 40 ± 0.05°C

S. No.	Name of the Soap	CMC (g mol L ⁻¹)	Garnsey's constant G x 10 ⁻⁵	$\begin{array}{c} \text{Constant} \\ A \times 10^{11} \end{array}$	$\begin{array}{c} \text{Constant} \\ \text{B} \times 10^{11} \end{array}$	$-\phi k^{o} \times 10^{-1}$	$-\phi^0 V \times 10^{-3}$
1	Butyrate	0.021	1.95	40	+ 175	6.5	1.22
2	Valerate	0.018	2.77	72	+ 125	9.4	2.42

The adiabatic compressibility, β , of the dilute solution of dysprosium soaps is found to obey Bachem's¹⁶ relationship.

 $\beta = \beta_0 + AC + BC^{3/2}$

where A and B are constants and C is the concentration of soap solution. The values of A for dysprosium soaps increase while B decrease with the increase in atomic mass of metal ion in the soap (Table-3)

The values of limiting apparent molar compressibility ϕ_k have been obtained by extrapolating the linear portion of the plots of $\phi_k vs. C^{1/2}$ and found to increase with molecular weight if the dysprosium soap (Table-3). The values of ϕ_k are negative for all the solutions.

ACKNOWLEDGEMENT

The authors are thankful to Dr. B. K. Agarwal, Principal, Raja Balwant Singh College, Agra, for providing necessary facilities.
