#### Abstract

The kinetics of oxidation of 2-(2-methoxyethoxy)ethanol and 2-(2-ethoxyethoxy)ethanol by diperiodatocuprate(III) (DPC) in alkaline liquids had been investigated spectrophotometrically in the temperature range of $20^{\circ} \mathrm{C}$ to $40^{\circ} \mathrm{C}$. It was found that the reaction was pseudofirst order in [DPC] and $1<\mathrm{n}_{\mathrm{ap}}<2$ in the concentration of reductants. The pseudo-first order rate constant $\mathrm{k}_{\mathrm{obs}}$ decreased rapidly with an increase in $\left[\mathrm{OH}^{-}\right]$to a certain value, then increasing with the continuous increase in $\left[\mathrm{OH}^{-}\right]$. In addition, the $\mathrm{k}_{\mathrm{obs}}$ decreased with an increase in $\left[\mathrm{IO}_{4}^{-}\right]$. There was no salt effect. The rate of 2-(2-ethoxyethoxy)ethanol was higher than 2-(2-methoxyethoxy)ethanol in stronger alkaline medium. A plausible mechanism involving pre-equilibriums before the rate controlling step and a free radical mechanism was proposed from the kinetics study. The rate equations derived from mechanism can explain all experimental phenomena. Moreover, the activation parameters at 298.2 K along with rate constants of the rate-determining step were calculated.

Key Words: Kinetics, Oxidation, Diperiodatocuprate(III), 2-(2-Methoxyethoxy)ethanol, 2-(2-Ethoxyethoxy)ethanol.

## INTRODUCTION

In recent years, studies on the transition metals in a higher oxidation state have been the most active area. Transition metals generally can be stabilized by chelation with polydentate ligands, such as ditelluratocuprate(III) ${ }^{1,2}$, diperiodato-cuprate(III) ${ }^{3,4}$, diperiodatoargentate(III) ${ }^{5,6}$, ditelluratoargentate(III) ${ }^{7}$, diperiodatonickelate(IV) ${ }^{8}$ are good oxidants in a medium with an appropriate pH . As a kind of oxidation reagents, Cu (III) complex has been used widely in many biological systems involving electron-transfer processes ${ }^{9}$ and organic mixture qualitative analysis ${ }^{10}$. Because $\mathrm{Cu}(\mathrm{III})$ is in the highest oxidation state and the reaction is complicated in the kind of reaction system, it is of significance to have a further study on this kind of reaction system. In the present paper, the mechanism of oxidation of 2-(2-methoxyethoxy)ethanol and 2-(2-ethoxyethoxy)ethanol by diperiodatocuprate(III) is reported.

Both 2-(2-methoxyethoxy)ethanol and 2-(2-ethoxyethoxy)ethanol (EEE) are colourless liquids and high boiling-point solvents so that they have a wide application. Such as printing, dyeing, resin, cellulose and coatings, etc. In addition, 2-(2methoxyethoxy)ethanol can be used for the extracting agent for hydrocarbon and chemical reagent in chemical analysis.

## EXPERIMENTAL

All the reagents used were A.R. Grade and doubledistilled water was used throughout the work. Diperiodato-
cuprate(III) (DPC) was prepared and standardized by the method reported by Jaiswal ${ }^{11}$. The purity of the complex was checked by comparing UV-visible spectrum with literature data, which showed a characteristic absorption peak at $415 \mathrm{~nm} . \mathrm{KNO}_{3}$ and KOH were used to maintain ionic strength and alkaliniy of the reaction, respectively. Moreover, solutions of DPC and reductants were always freshly prepared before use.

Kinetics measurements and apparatus: The kinetics were followed under pseudo-first order conditions, solution ( 2 mL ) containing required concentration of $\mathrm{DPC}, \mathrm{OH}^{-}, \mathrm{IO}_{4}^{-}$and ionic strength and reductant solution $(2 \mathrm{~mL})$ of requisite concentration were mixed at the desired temperature. The progress of the reaction was followed by measuring the decrease in absorbance of DPC at 415 nm . The kinetic measurements were performed on a UV-visible spectrophotometer (TU-1900, Beijing Puxi Inc., China), which had a cell holder kept at constant temperature ( $\pm$ $0.1^{\circ} \mathrm{C}$ ) by circulating water from a thermostat (DC-2010, Baoding Xinhua Inc., China). It was verified that there was negligible interference from other reagents at this wavelength.

## RESULTS AND DISCUSSION

Product analysis: Under the kinetic conditions the product of oxidation was identified as aldehyde by its characteristic spot test ${ }^{12}$.

Evaluation of pseudo-first order rate constants: Under the conditions of $[\text { reductant }]_{0}\left([\mathrm{MEE}]_{0}\right.$ and $\left.[E E E]_{0}\right) \gg$
$[\mathrm{Cu}(\mathrm{III})]_{0}$, the plots of $\ln \left(\mathrm{A}_{\mathrm{t}}-\mathrm{A}_{\infty}\right)$ versus time were straight $\operatorname{lines}(r \geq 0.999)$ (Fig. 1), indicating the order in DPC to be unity. The pseudo-first-order rate constants $\mathrm{k}_{\text {obs }}$ were evaluated by using the equation $\ln \left(\mathrm{At}-\mathrm{A}_{\infty}\right)=-\mathrm{k}_{\text {obst }}+\mathrm{b}$ (constant). The $\mathrm{k}_{\text {obs }}$ values were the average value of at least three independent experiments and reproducibility was within $\pm 5 \%$.

Fig. 1. Plot of $\ln \left(\mathrm{A}_{\mathrm{t}}-\mathrm{A}_{\infty}\right) v s t$ at $\mathrm{T}=298.2 \mathrm{~K} ;[\mathrm{DPC}]=6.99 \times 10^{-5} \mathrm{~mol} \mathrm{~L}^{-1}$, $\left[\mathrm{IO}_{4}^{-}\right]=1.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}, \mu=3.11 \times$ $10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$, [reductant] $=4.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}(1)$ [MEE]: $\mathrm{k}_{\text {obs }}=1.512$ $\times 10^{-3} \mathrm{~s}^{-1}(2)[\mathrm{EEE}]: \mathrm{k}_{\text {obs }}=1.904 \times 10^{-3} \mathrm{~s}^{-1}$

Rate dependence on the [reductant]: The [reductant] was varied in the range of $0.25 \mathrm{~mol} \mathrm{~L}^{-1}$ to $0.60 \mathrm{~mol} \mathrm{~L}^{-1}$ at different temperature keeping all other [reactants] constant. The order nap of [reductant] was found to be $1<\mathrm{n}_{\text {ap }}<2$ form the slopes of $\ln \mathrm{k}_{\text {obs }}$ versus $\ln [$ reductant] plots. Besides, the $\mathrm{k}_{\text {obs }}$ value increased with the increasing [reductant]. The plots of [reductant] $/ \mathrm{k}_{\text {obs }}$ versus $1 /[$ reductant] were straight lines ( $\mathrm{r}=$ 0.998) (Figs. 2 and 3).

Rate dependence on the $\left[\mathrm{OH}^{-}\right]$: The effect of $\left[\mathrm{OH}^{-}\right]$on the reaction had been studied in the range of $5.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$

Fig. 2. Plots of $[\mathrm{MEE}] / \mathrm{k}_{\mathrm{obs}}{ }^{-1} \mathrm{vs}$. $[\mathrm{MEE}]^{-1}(\mathrm{r}=0.998) \cdot[\mathrm{DPC}]=6.99 \times 10^{-5}$ $\mathrm{mol} \mathrm{L}{ }^{-1},\left[\mathrm{IO}_{4}^{-}\right]=1.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}, \mu$ $=3.11 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$

Fig. 3. Plots of $[\mathrm{EEE}] / \mathrm{k}_{\mathrm{obs}}{ }^{-1}$ vs. $[\mathrm{EEE}]^{-1}(\mathrm{r}=0.998) ;[\mathrm{DPC}]=6.99 \times 10^{-5}$ $\mathrm{mol} \mathrm{L}{ }^{-1},\left[\mathrm{IO}_{4}^{-}\right]=1 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}, \mu=$ $3.11 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$
to $25.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$ at constant [DPC], [reductant], $\left[\mathrm{IO}_{4}^{-}\right.$], $\mu$ and temperature. It was found that $\mathrm{k}_{\text {obs }}$ decreased rapidly with the increaseing $\left[\mathrm{OH}^{-}\right]$to a certain value, then increasing with the continuous increase in $\left[\mathrm{OH}^{-}\right]$. The plot of $\mathrm{k}_{\text {obs }} v s .\left[\mathrm{OH}^{-}\right]$was curved line (Fig. 4). The concentration of $\mathrm{OH}^{-}$was about 7.50 $\times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$ for MEE at the turning point in which the rate was the slowest, but $\left[\mathrm{OH}^{-}\right]$was about $2.50 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$ with respect to EEE at the turning that the rate was the slowest.

Fig. 4. Plots of $10^{2} \mathrm{k}_{\text {obs }}$ vs. $10^{2}\left[\mathrm{OH}^{-}\right]$at $303.2 \mathrm{~K} ;[\mathrm{DPC}]=6.99 \times 10^{-5} \mathrm{~mol} \mathrm{~L}^{-1}$, $\left[\mathrm{IO}_{4}^{-}\right]=1.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}, \mu=3.11 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$, [reductant] $=$ $4.00 \times 10^{-1} \mathrm{~mol} \mathrm{~L}^{-1}$, (1) [MEE] (2)[EEE]

Rate dependence on the $\left[\mathrm{IO}_{4}^{-}\right]$: The $\left[\mathrm{IO}_{4}^{-}\right]$was varied from $1.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$ to $3 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$ range at constant [DPC], [reductant], $\left[\mathrm{OH}^{-}\right], \mu$ and temperature. The $\mathrm{k}_{\text {obs }}$ values increased with the decreasing concentration of $\mathrm{IO}_{4}^{-}$. The order with respect to $\mathrm{IO}_{4}^{-}$was found to be a negative fraction, which reveals that $\mathrm{IO}_{4}^{-}$was produced in equilibrium before the rate controlling step. A plot of $\mathrm{k}_{\text {obs }}{ }^{-1}$ versus $\left[\mathrm{IO}_{4}^{-}\right]$was straight line with a positive intercept (Fig. 5).

Fig. 5. Plots of $\mathrm{k}_{\mathrm{obs}}{ }^{-1}$ vs. $10^{2}\left[\mathrm{IO}_{4}^{-}\right]$at $303.2 \mathrm{~K},(\mathrm{r}=0.998) ;[\mathrm{DPC}]=6.99 \times$ $10^{-5} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}, \mu=3.11 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$, [reductant] $=4.00 \times 10^{-1} \mathrm{~mol} \mathrm{~L}^{-1}(1)$ [MEE] (2)[EEE]

Rate dependence on ionic strength ( $\boldsymbol{\mu}$ ): The effect of ionic strength on the reaction was studied in the range of 1.50 $\times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$ to $7.50 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1}$ at constant [DPC], [reduc-$\operatorname{tant}],\left[\mathrm{OH}^{-}\right],\left[\mathrm{IO}_{4}^{-}\right]$and temperature. The experimental results indicated that the rate constant $\mathrm{k}_{\text {obs }}$ changed slightly with increased in ionic strength ( $\mu$ ) (Table-1), which showed that there was no salt effect.

## TABLE-1

INFLUENCE OF VARIATION IONIC STRENGTH $(\mu)$ AT 303.2 K

| $10^{2} \mu / \mathrm{mol} \mathrm{L}^{-1}$ |  | 1.50 | 3.00 | 4.50 | 6.00 | 7.50 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | EEE | 24.75 | 24.90 | 25.35 | 26.03 | 26.42 |

[reductant] $([\mathrm{MEE}]$ and $[\mathrm{EEE}])=4.00 \times 10^{-1} \mathrm{~mol} \mathrm{~L}^{-1},[\mathrm{DPC}]=6.99 \times$
$10^{-5} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{IO}_{4}^{-}\right]=1.00 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1}$

Free radical detection: To study the possible presence of a free radical during the reaction, a known amount of acrylamide was added under the protection of nitrogen atmosphere. The polymerization clearly appeared which indicated that free radical intermediates may be produced in the oxidation by DPC. And blank experiments in reaction system gave no polymeric suspensions.

Reaction mechanism: In aqueous periodate solution, equilibria (1)-(3) were detected and the corresponding equilibrium constants at 273.2 K were determined by Aveston ${ }^{13}$.

$$
\begin{gather*}
2 \mathrm{IO}_{4}^{-}+2 \mathrm{OH}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{I}_{2} \mathrm{O}^{4}{ }_{10} \log \beta_{1}=15.05  \tag{1}\\
\mathrm{IO}_{4}^{-}+\mathrm{OH}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{IO}_{6}{ }^{3-} \log \beta_{2}=6.21  \tag{2}\\
\mathrm{IO}_{4}^{-}+2 \mathrm{OH}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{IO}_{6}^{3-} \log \beta_{3}=8.67 \tag{3}
\end{gather*}
$$

The distribution of all species of periodate in aqueous alkaline solution can be calculated from equilibriums (1)-(3). In the concentration of $\mathrm{OH}^{-}$range used in this work the dimer and $\mathrm{IO}_{4}^{-}$species of periodate can be neglected. The equations (4)-(5) can be obtained from (2) and (3) as below:

$$
\begin{align*}
& {\left[\mathrm{H}_{2} \mathrm{IO}_{6}^{3-}\right]=\frac{\beta_{3}\left[\mathrm{OH}^{-}\right]^{2}}{1+\beta_{2}\left[\mathrm{OH}^{-}\right]+\beta_{3}\left[\mathrm{OH}^{-}\right]^{2}}\left[\mathrm{IO}_{4}^{-}\right]_{\mathrm{ex}}=\mathrm{f}\left(\left[\mathrm{OH}^{-}\right]\right)\left[\mathrm{IO}_{4}^{-}\right]_{\mathrm{ex}}} \\
& {\left[\mathrm{H}_{3} \mathrm{IO}_{6}^{2-}\right]=\frac{\beta_{2}\left[\mathrm{OH}^{-}\right]}{1+\beta_{2}\left[\mathrm{OH}^{-}\right]+\beta_{3}\left[\mathrm{OH}^{-}\right]^{2}}\left[\mathrm{IO}_{4}^{-}\right]_{\mathrm{ex}}=\phi\left(\left[\mathrm{OH}^{-}\right]\right)\left[\mathrm{IO}_{4}^{-}\right]_{\mathrm{ex}}} \tag{5}
\end{align*}
$$

here $\left[\mathrm{IO}_{4}^{-}\right]_{\text {ex }}$ representsed the concentration of original overall periodate and equals approxinately to the sum of $\left[\mathrm{H}_{2} \mathrm{IO}_{6}{ }^{3-}\right]$ and $\left[\mathrm{H}_{3} \mathrm{IO}_{6}{ }^{2-}\right]$.

In weaker alkaline medium such as $\left[\mathrm{OH}^{-}\right]=5.00 \times 10^{-3}$ $\mathrm{mol} \mathrm{L}{ }^{-1},\left[\mathrm{H}_{2} \mathrm{IO}_{6}{ }^{3-}\right]:\left[\mathrm{H}_{3} \mathrm{IO}_{6}{ }^{2-}\right]=1.44: 1.00$, so the main species of periodate were $\mathrm{H}_{2} \mathrm{IO}_{6}{ }^{3-}$ and $\mathrm{H}_{3} \mathrm{IO}_{6}{ }^{2-}$, consistent with the result calculated from Crouthamel's data by Murthy ${ }^{14}$. In stronger alkaline medium such as $\left[\mathrm{OH}^{-}\right]=5.00 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1},\left[\mathrm{H}_{2} \mathrm{IO}_{6}{ }^{3-}\right]$ : $\left[\mathrm{H}_{3} \mathrm{IO}_{6}{ }^{2-}\right]=14.40: 1.00$, so the main species of periodate was $\mathrm{H}_{2} \mathrm{IO}_{6}{ }^{3-}$.

According to the above discussion, the two plausible mechanisms of oxidation were proposed as follows: ( R respectively standed for MEE and EEE; R' respectively standed for $\mathrm{OCH}_{3}$ and $\mathrm{OCH}_{2} \mathrm{CH}_{3}$ ).

Mechanism I ----In weaker alkaline medium:
$\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)_{2}\right]^{3-}+3 \mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{K}_{1}}{=}\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]+\mathrm{H}_{3} \mathrm{IO}_{6}^{2-}+\mathrm{OH}^{-}(6)$

$$
\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]+\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{R} \stackrel{\mathrm{~K}_{2}}{\rightleftharpoons}
$$

$\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)\left(\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{R}\right]+2 \mathrm{H}_{2} \mathrm{O}\right.$

$$
\begin{equation*}
\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)(\mathrm{R})\right]+[\mathrm{R}] \xrightarrow[\text { slow }]{\mathrm{k}_{2}} \tag{7}
\end{equation*}
$$

$$
\begin{gather*}
\mathrm{Cu}(\mathrm{II})+\stackrel{\stackrel{\mathrm{C}}{\mathrm{C}} \mathrm{H}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{R}^{\prime}(\mathrm{R})}{ }  \tag{8}\\
\mathrm{Cu}^{*}(\mathrm{IIII})+\stackrel{\stackrel{\mathrm{C}}{\mathrm{C}} \mathrm{H}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{R}^{\prime}(\mathrm{R})+\mathrm{OH}^{-} \xrightarrow[\text { fast }]{\mathrm{Ku}(\mathrm{II})+\mathrm{HCOCH}_{2} \mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{R}^{\prime}+\mathrm{R}+\mathrm{H}_{2} \mathrm{O}}}{ }
\end{gather*}
$$

The $\mathrm{Cu}^{*}$ (III) stand for any kind of which $\mathrm{Cu}^{3+}$ existed in equilibrium. The total concentration of $\mathrm{Cu}(\mathrm{III})$ can be written as:(subscripts T and e stand for total concentration and at equilibrium respectively).
$\mathrm{Cu}{ }^{*}(\mathrm{III})=\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{\mathrm{e}}+\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)_{2}\right]^{3-}+\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)(\mathrm{R})\right]_{\mathrm{e}}$
Since reaction (8) was the rate-determining step, the rate of disappear of $[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}}$ was represented as:

$$
\begin{align*}
-\frac{\mathrm{d}[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}}}{\mathrm{dt}}= & \frac{2 k_{1} K_{l} K_{2}[\mathrm{R}]^{2}}{K_{1}+\left[\mathrm{H}_{3} \mathrm{IO}_{6}{ }^{2-}\right]\left[\mathrm{OH}^{-}\right]+K_{l} K_{2}[\mathrm{R}]}[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}} \\
= & k_{\text {obs }}[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}}  \tag{10}\\
& k_{\text {obs }}=\frac{2 k_{1} K_{1} K_{2}[\mathrm{R}]^{2}}{K_{l}+\left[\mathrm{H}_{3} \mathrm{IO}_{6}^{2-}\right]\left[\mathrm{OH}^{-}\right]+K_{1} K_{2}[\mathrm{R}]} \tag{11}
\end{align*}
$$

Re-arranging eqn. (11) leaded to eqns. (12) and (13)

$$
\begin{gather*}
\frac{[\mathrm{R}]}{k_{\text {obs }}}=\frac{1}{2 k_{l}}+\frac{K_{1}+\left[\mathrm{H}_{3} \mathrm{IO}_{6}^{2-}\right]\left[\mathrm{OH}^{-}\right]}{2 k_{1} K_{1} K_{2}} \times \frac{1}{[\mathrm{R}]}  \tag{12}\\
\frac{1}{k_{\text {obs }}}=\frac{K_{l} K_{2}[\mathrm{R}]+K_{1}}{2 k_{1} K_{1} K_{2}[\mathrm{R}]^{2}}+\frac{\left[\mathrm{OH}^{-}\right]}{2 k_{1} K_{1} K_{2}[\mathrm{R}]^{2}} \times\left[\mathrm{H}_{3} \mathrm{IO}_{6}^{2-}\right] \tag{13}
\end{gather*}
$$

Mechanism II---In stronger alkaline medium:

$$
\begin{gather*}
{\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)_{2}\right]^{3-}+\mathrm{OH}^{-} \stackrel{K_{3}}{\rightleftarrows}\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)\right]^{-}+\mathrm{H}_{2} \mathrm{IO}_{6}^{3-}+\mathrm{H}_{2} \mathrm{O}}  \tag{14}\\
{\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)\right]+R \stackrel{K_{s}}{\rightleftarrows}\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)(\mathrm{R})\right]} \tag{15}
\end{gather*}
$$

$\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)(\mathrm{R})\right]+[\mathrm{R}] \xrightarrow{\frac{k_{2}}{\text { slow }} \mathrm{Cu}(\mathrm{II})+\dot{\mathrm{C}} \mathrm{H}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{R}^{\prime}(\mathrm{R})(16) ~}$

$$
\mathrm{Cu} *(\mathrm{III})+\dot{\mathrm{C}} \mathrm{H}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{R}^{\prime}(\mathrm{R})+\mathrm{OH}^{-}
$$

$$
\begin{equation*}
\xrightarrow{k_{f} \text { fast }} \mathrm{Cu}(\text { II })+\mathrm{HCOCH}_{2} \mathrm{OC}_{2} \mathrm{H}_{4} \mathrm{R}^{\prime}+\mathrm{R}+\mathrm{H}_{2} \mathrm{O} \tag{17}
\end{equation*}
$$

where $\mathrm{Cu}^{*}$ (III) stand for any kind of form which $\mathrm{Cu}(\mathrm{III})$ existed in equilibrium. The total concentration of $\mathrm{Cu}(\mathrm{III})$ can be written as:(subscripts T and e stand for total concentration and at equilibrium respectively).
$\mathrm{Cu}^{*}(\mathrm{III})=\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)\right]_{\mathrm{e}}^{-}+\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{IO}_{6}\right)_{2}\right]_{\mathrm{e}}^{3-}+\left[\mathrm{Cu}\left(\mathrm{HIO}_{6}\right)(\mathrm{R})\right]_{\mathrm{e}}$
Reaction (17) was the rate-determining step. Similarly, the rate of the reaction can be derived as:

$$
\begin{align*}
-\frac{\mathrm{d}[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}}}{\mathrm{dt}} & =\frac{2 k_{2} K_{3} K_{4}\left[\mathrm{OH}^{-}\right][\mathrm{R}]^{2}}{K_{3}\left[\mathrm{OH}^{-}\right]+\left[\mathrm{H}_{2} \mathrm{IO}_{6}^{3-}\right]+K_{3} K_{4}\left[\mathrm{OH}^{-}\right][\mathrm{R}]}[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}} \\
& =k_{\text {obs }}[\mathrm{Cu}(\mathrm{III})]_{\mathrm{T}}  \tag{18}\\
& k_{\text {obs }} \tag{19}
\end{align*}=\frac{2 k_{2} K_{3} K_{4}\left[\mathrm{OH}^{-}\right][\mathrm{R}]^{2}}{K_{3}\left[\mathrm{OH}^{-}\right]+\left[\mathrm{H}_{2} \mathrm{O}_{6}^{3-}\right]+K_{3} K_{4}\left[\mathrm{OH}^{-}\right][\mathrm{R}]} .
$$

Re-arranging equation (19) leaded to equations (20) and (21).

$$
\begin{align*}
& \frac{[\mathrm{R}]}{k_{\text {obs }}}=\frac{1}{2 k_{2}}+\frac{K_{3}\left[\mathrm{OH}^{-}\right]+\left[\mathrm{H}_{2} \mathrm{IO}_{6}^{3-}\right]}{2 k_{2} K_{3} K_{4}\left[\mathrm{OH}^{-}\right]} \times \frac{1}{[\mathrm{R}]}  \tag{20}\\
& \frac{1}{k_{\text {obs }}}=\frac{K_{3} K_{4}[\mathrm{R}]+K_{3}}{2 k_{2} K_{3} K_{4}[\mathrm{R}]^{2}}+\frac{\left[\mathrm{H}_{2} \mathrm{IO}_{6}^{3-}\right]}{2 k_{2} K_{3} K_{4}\left[\mathrm{OH}^{-}\right][\mathrm{R}]^{2}} \tag{21}
\end{align*}
$$

Equations (1)-(5) and our calculated results were given, which can explain why $\mathrm{k}_{\text {obs }}$ decreased rapidly with increase in [ $\mathrm{OH}^{-}$] up to a certain value. After the point, it increased gradually with the continuous increasing in $\left[\mathrm{OH}^{-}\right]$.

Equations (10) and (18) suggested that the order with respect to Cu (III) was unity. Eqns. (11) and (19) showed that the order in [reductant] was found to be $1<\mathrm{n}_{\mathrm{ap}}<2$. The rate constants of the rate-determining step at different temperature were determined by the intercept of the plots of [reductant]/ $\mathrm{k}_{\text {obs }} v s .1 /[$ reductant] which were straight lines. Eqns. (13) and (21) showed that the plots of $1 / \mathrm{k}_{\text {obs }}$ versus $\left[\mathrm{IO}_{4}^{-}\right]$should also be linear. The rate equations derived from the two simultaneous mechanisms were consistent with our experimental results. Hence activation energy and the thermodynamic parameters were evaluated at 298.2 K by the method given earlier ${ }^{15}$ (Table$2)$.

| TABLE-2 |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| RATE CONSTANTS ( $k$ C) AND ACTIVATION PARAMETERS |  |  |  |  |  |
| OF THE RATE-DETERMINING STEP |  |  |  |  |  |$]$.

The plot of $\ln \mathrm{k}$ vs $1 / \mathrm{T}$ have following intercept (a) slope (b) and relative coefficient (r); MEE: $\mathrm{a}=6.54, \mathrm{~b}=-3727.05, \mathrm{r}$ $=-0.995$; EEE: $\mathrm{a}=5.12, \mathrm{~b}=-3197.63, \mathrm{r}=-0.995$.

## Conclusion

Through the comparative study of oxidation of 2-(2methoxy ethoxy)ethanol (MEE) and 2-(2-ethoxyethoxy)ethanol (EEE) by diperiodatocuprate(III), it is found that both the MEE and EEE formed the same intermediate compounds with $\mathrm{Cu}(\mathrm{III})$. In addition, the values of the activation parameters with respect to MEE is larger than that of EEE, which indicated the reactivity of EEE is higher than MEE. The reason is that the electron-donating ability of EEE is larger than that of MEE. Moreover, The transition complex formation between EEE and DTA is more stable than that of MEE. The above conclusions are consistent with experimental results.
