AJC-12679

The purpose of this study was to determine which of the quantum chemistry methods PM3, HF and DFT/B3LYP evaluate more accurately the geometric parameters of two terpenoids 18 $\alpha$ -oleanane (**1**) and A-neo-18 $\alpha$ -oleanene (**2**). The theoretical results were compared to experimental data generated by X-ray diffraction. Compound **1**, C<sub>33</sub>H<sub>52</sub>O<sub>3</sub>, crystallizes in space group C2 with *a* = 13.3520 (2), *b* = 6.54000 (10), *c* = 32.4439(5) Å, *V* = 2798.13(7) Å<sup>3</sup> and *Z* = 4. The structure was refined to a final *R* = 0.027 for the structure factors observed with *I* ≥ 3σ(*I*). The second molecule **2**, C<sub>30</sub>H<sub>46</sub>O<sub>2</sub>, crystallizes in the monoclinic space group with *a* = 13.2214 (4), *b* = 6.4962 (2), *c* = 29.8420(9) Å, *V* = 2558.00(13) Å<sup>3</sup> and *Z* = 4. The structure was refined to a final *R* = 0.061 for the structure factors observed with *I* = 2σ(*I*). A comparative study using *ab initio* calculation (HF/6-31G\*\*), semi empirical (PM3) and DFT(B3LYP/6-31G\*\*) shows a high correlation with the geometric data of X-ray diffraction. The difference between the calculated and experimental values is very insignificant.

**Key Words:** PM3, HF, DFT, Terpenoids, X-Ray.

### INTRODUCTION

Plants produce a wide range of natural products, including terpenoids, steroids, saponins, alkaloids, flavonoids, coumarins and tannin. Many of which possess potent biological activity. Several molecules isolated from nature are currently under study at an advanced stage of clinical trials, either directly or in the form of analogues deduced from structure-activity relation ships<sup>1</sup>. A vast series of natural terpenoids are widely distributed in nature and exhibit great structural and biological diversity and are commonly found in vascular plants from various families. They are present at different levels of abundance in all plant parts. Terpenoids are of considerable pharmacological and clinical interest and are used as models for the design of molecules having useful activities (antitumor, antiviral, antibacterial, hepatoprotective, antioxidant, antiulcer and antiallergen)<sup>2</sup>. During the last decade, increasing attention has focused on new and appropriate methods for the analysis of terpenoids from plant sources. Conventional chromatographic methods, HPLC, LC-NMR GC-MS still remain the most useful and most commonly applied techniques<sup>3</sup>. Although structural elucidation of terpenoids is not a difficult task, the similarities between the structures can create problems. In particular, the determination of stereochemistry requires NOE/NOESY NMR

experiments and/or X-ray analyses. Multidisciplinary efforts of chemist, biochemists and medicinal chemists have led to new developments in the field of terpenoids, which are based primarily on the physical and chemical properties include selective reactivity towards various reagents and the possibilities for functionalization and derivatization of these natural compounds<sup>4</sup>. However, to the best of our knowledge, there is little published information describing the X-ray crystallography of these compounds<sup>5</sup>. Compared to flavonoids which have been widely investigated<sup>6-8</sup>.

In continuation of our work to the characterization of natural products<sup>9-11</sup>, we present in this study a theoretical determination of the geometric parameters of 18 $\alpha$ -oleanane and A-neo-18 $\alpha$ -oleanene at semi-empirical PM3<sup>12</sup>, *ab initio* HF<sup>13</sup> and DFT levels<sup>14</sup>. We used 6-31G(d,p) bases set. The functional B3LYP<sup>15</sup> was used in DFT calculation. This procedure has been efficiently employed in the structural determination of diterpenoids<sup>16</sup> and other organic compounds<sup>17,18</sup>. The studied terpenoids were selectively prepared by Salvador *et al.*<sup>4</sup> under Wagner-Meerwein rearrangement of lupane terpenoid by using bismuth(III) salts as catalysts. The physical data (IR, MS, NMR and X-ray crystallography) of obtained compounds were indicated<sup>4</sup>. So, we have used the experimental X-ray diffraction data in our theoretical approach.

## COMPUTATIONAL METHOD

All the calculations were carried out using software package Gaussian 98<sup>19</sup>. Quantum chemical methods at the PM3, DFT and HF level were used to determine the optimal geometry and energies of two terpenoids  $18\alpha$ -oleanane and A-neo- $18\alpha$ -oleanene. In DFT calculations the functional B3LYP was used with standard Pople's split valence 6-31G(d,p) basis set<sup>15</sup>. Such combination is being used with good results for organic hydrogen-bonded systems<sup>20,21</sup>. It represents a good compromise between economy of computational resources, accuracy and applicability to many-atoms molecules. The 6-31G(d,p) basis set was used in the HF calculations. The optimized geometries were characterized as true minima on the potential energy surface (PES) since all harmonic frequencies were real. *Ab initio* geometry optimization on  $18\alpha$ -oleanane ( $C_{32}H_{52}O_3$ ) and A-neo- $18\alpha$ -oleanene ( $C_{30}H_{46}O_2$ ) was performed starting from the geometry found in the X-ray refinement.

## RESULTS AND DISCUSSION

**Structure of the compound 1 ( $C_{32}H_{52}O_3$ ):** The displacement ellipsoid plot with the numbering scheme for the compound **1** is shown in Fig. 1. Selected X-ray diffraction data summarize bond lengths, bond angles and torsion angles in Tables 1-3, respectively.

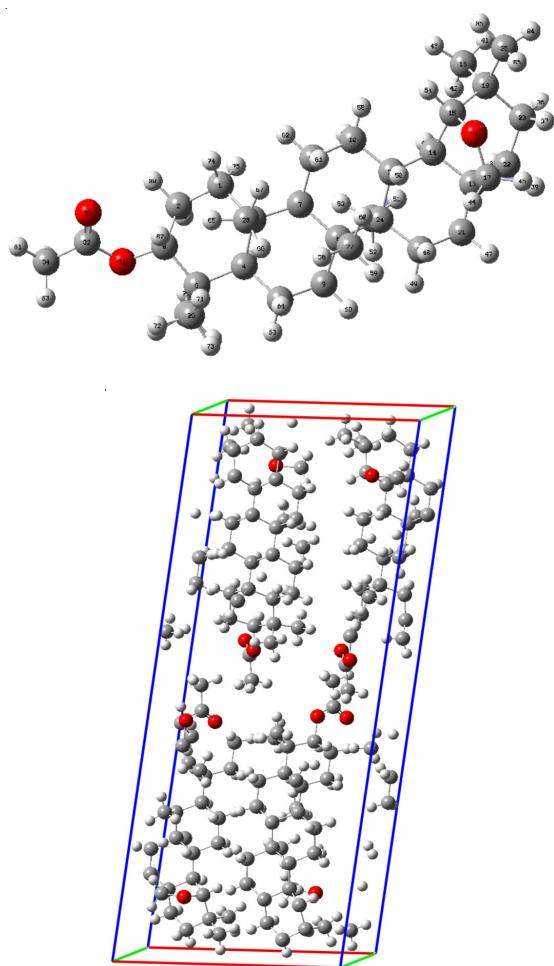

Fig. 1. Perspective view of the molecule **1** and the crystal packing in the unit cell (displacement ellipsoids are drawn at the 50 % probability level, H atoms of arbitrary sizes)

In order to establish the accuracy of HF/6-31G (d,p),PM3 and B3LYP/6-31G (d,p) models chemistry in the reproducibility of structural properties of the  $18\alpha$ -oleanane, the computational data were compared with the experimental data taken from work of Salvador *et al.*<sup>4</sup>. The computational data are generated for the gas phase and compared with the solid state ones because the only experimental data found in the literature were from an X-ray study. Molecules optimized with B3LYP/6-31G (d,p) model indicating that both molecules are into their minimum values of energy.

The results showed in Tables 1 and 2 reveal a general similitude between theoretically and experimentally calculated bond distances and bond angles for  $18\alpha$ -oleanane. The theoretical and experimental C-C and C-O bond distances present small differences; using HF/6-31G (d,p) method data in the order of 0.00-0.03 Å, in the order of 0.001-0.02 Å using DFT/B3LYP/6-31G (d,p) method data and in the order of 0.001-0.03 Å using PM3 method data, while the C-H bond distances show noticeable differences using the three methods of calculation, respectively in a range of 0.102-0.127, 0.115-0.136 and 0.130-0.148 Å.

The large differences in the solid state can be attributed to the fact that C-H groups constituted the site for the intermolecular interactions and hydrogen bonds with the water of the crystal lattice. Oppositely, in the simulation is modeled a single molecule free of intermolecular interactions, therefore the bond distances are almost not modified.

The theoretical and experimental bond angles between carbon atoms in first molecule present differences about 0.02 to 1.92° used HF/6-31G (d,p) 0.00 to 2.55° used B3LYP/6-31G (d,p) and around of 0.03 to 4.44° used PM3, when the PM3 method over estimates the bond angles. The presence of an oxygen atom diverted the experimental values around 0.4-1.6° with respect to the theoretical bond angle, such as the bond distances. Nevertheless the variations found, the standard deviations for bond distances and bond angles of two molecules were small (Tables 1 and 2), thus the B3LYP/6-31G (d,p) method give a good agreement between theoretical and experimental data. The torsion angles showed in Table-3, regularly are utilized to define the molecular planarity. However, their values tended to be 0° or 180°. The presence of oxygen atom originates a great deviation of the angle in a range of 4-8°.

**Structure of the compound 2 ( $C_{30}H_{46}O_2$ ):** The displacement ellipsoid plot with the numbering scheme for the title compound **2** is shown in Fig. 2. Selected X-ray diffraction data summarize bond lengths in Table-4, bond angles in Table-5 and torsion angles in Table-6.

The geometry of compound **2** has been fully optimized using PM3, the DFT method with the help of Becke's three parameter hybrid density functional, B3LYP/6-31G(d,p) and HF/6-31G(d,p), using Gaussian 98 program<sup>19</sup>. The results were compared with the X-ray data and show an excellent agreement (Tables 4-6), where the molecular structure is shown in Fig. 2. The largest deviation of the DFT optimized bond-lengths/angles from the corresponding X-ray experimental values is 14.06 % for C-H and 1.94 % for H-C-H .However the HF method data give the deviation between 14.85 % and

2.20 %, respectively. But using PM3 method data the difference is around 15.06 and 5.22 %. The differences observed between the theoretical and experimental results are probably due to packing effects. When we whereas the PM3 method over estimates the torsion angle.

### Conclusion

We have tested the PM3, HF and DFT methods to determine geometric parameters of two terpenoids 18 $\alpha$ -oleanane (**1**) and A-neo-18 $\alpha$ -oleanene (**2**). DFT/B3LYP/6-31G(d,p)

model chemistry can be considered as the most appropriate method to facilitate the reproducibility of structural properties in terpenoids compounds, because the bond distances, bond angles and torsion angles of the simulated molecules are generally adjusted to the experimental conformations taken from literature into a strict range of variation. The larger values than the corresponding experimental ones, due to the fact that theoretical calculations imply isolated molecules in gaseous phase state while experimental results refer to molecules in
