In this work, we present the result for electronic structure properties of the stavudine and it's 4'-substituents molecules that have involved pseudorotation angle parameters for five sugar member ring, frontal orbital, electrostatic potential maps and total energies, as well as, potential energy surfaces of exocylic rotation angles at DFT and ab initio level theories. Comparisons to D4T and 4'substituted ones have the major concern of this report. Five sugar member rings of syn conformers are more planar corresponding to anti ones and the substitution shows a different a trends on the two conformations. The substitution at C 4 ' position not cause a significant changes in gap values, whereas, the substitution lead to decrease dihedral angle $(\chi)$.

Key Words: DFT, Potential energy surface, Stavudine, Pseudorotation cycle, Puckering.

## INTRODUCTION

Human immunodeficiency virus type 1 (HIV-1) uses its own reverse transcriptase (RT) to convert its single stranded RNA genome into a double stranded DNA copy. zidovudine, didanosine, lamivudine (3TC) and stavudine (d4T) are considered the significant class of nucleoside reverse transcriptase inhibitors against HIV-1 infection ${ }^{1-4}$. The modified nucleosides of pyrimidine bases subjected to many studies as potential agent modified nucleosides of pyrimidine bases subjected to many investigations as potential antiviral agents ${ }^{5-9}$. Unfortunately the clinically applications of these compounds is confined with limits due to their cytotoxicity through inhibition the host DNA polymerase ${ }^{9,10}$ and the rapid emergence of drugresistant viral mutants. Therefore the studies to physico-chemical properties mad help to understand the behavour of new classes with reduced cytotoxicity and improved antiviral potency, particularly against drug-resistance viral strains ${ }^{11-13}$. Our work employs conventional ab initio and DFT calculations to introduce a systematic investigation for D4T and it's new noval analogs which are synthesized by Dutschman et al. ${ }^{14}$ (Fig. 1) shows schematic structures of these molecules.

It's important to know the electronic structure to such flexible systems. The object of this study is to investigate the most electronic structure properties for such important molecules and if there a significant difference in electronic structure properties resulting from substituent on C 4 ' pentofuranosyl position.

Fig. 1. Structural formula for 4'-substituted D4T
An investigation on the effect of the solvent on the molecular structure and energetics of the most stable conformers of stavudine and thymidine was carried out ${ }^{15}$, followed by a study ${ }^{16}$ of the tautomerism of this analogs by using the B3LYP and MP2 quantum chemical methods.

The conformation of nucleoside is usually referred by four vital structural parameters ${ }^{17,18}$ the phase angle of pseudorotation

P , describing the puckering of the furanose ring: the north conformer with $-90^{\circ} \leq \mathrm{P} \leq 90^{\circ}$ and the south conformer with $90^{\circ} \leq \mathrm{P} \leq 270^{\circ}$, the glycosilic torsion angle $\chi$ (anti or syn), orientation of exocyclic chain above the ring C 4 '-C5' and orientation of groups attached to pyrimidine moiety. Pseudorotation wheel (Fig. 2) has been used to describe modes of five sugar member ring and pseudorotational phase angle $(\mathrm{P})$ and the maximum puckering amplitude $\left(\mathrm{V}_{\max }\right)$ are calculated from eqns. 1 and 2.

Fig. 2. Pseudorotation wheel for pentofuranosyl nucleosides denotes "twist" and E denotes "envelope". The units of the P and $\nu_{\max }$ are degrees. The radius of the wheel corresponds to $v_{\text {max }}$ and the small concentric circle encompasses a central region characterized by a flatter sugar moiety $\left(v_{\max }<20^{\circ}\right)$

Since the arctan function produces angles in the range of $-90^{\circ}$ to $90^{\circ}, 180^{\circ}$ is added to $\arctan (\mathrm{p})$ when $\mathrm{V}_{2}$ is negative to obtain the P values in the range of $90-270^{\circ}$ (south); $360^{\circ}$ is added to $\arctan (\mathrm{p})$ in the remaining cases where p is negative to obtain P values in the range of $270-360^{\circ}$ (north).

$$
\begin{gather*}
\tan P=\frac{\left(v_{4}+v_{1}\right)-\left(v_{3}+v_{0}\right)}{2 v_{2}\left(\sin 36^{\circ}+\sin 72^{\circ}\right)}  \tag{1}\\
v_{\max }=o b s\left(\frac{v_{2}}{\cos \mathrm{P}}\right) \tag{2}
\end{gather*}
$$

## COMPUTATIONAL METHOD

- Becke three parameter hybrid exchange functionals B3 combined with LYP type correlation Functionals have been employed to find the equilibrium geometry with medium split valence basis sets $6-31 \mathrm{G}(\mathrm{d})$ and $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ using gradient technique without symmetry constrain the calculation results produced two minima anti and syn conformations with all gradient vectors have exactly zero.
- QST2 mythology, with B3lyp/6-31G(d) and by B3LYP/ $6311++\mathrm{G}(\mathrm{d}, \mathrm{p}) / / \mathrm{B} 31 \mathrm{lyp} / 6-31 \mathrm{G}(\mathrm{d})$ are employed to find the saddle point and to show height of intra-conversion barrier between two anti and syn conformers .
- Hessian matrix calculated with B3LYP(d) in order to identify the nature of stationary points, there is no any imaginary (negative) frequency onto the stationary points of the two minima, but, one negative eigenvalue of into Hessian matrix is recorded for transition state geometry.
- For accuracy purposes, we use single point calculations in many places. DFT [B3LYP,hybrid functional of Perdew, Burke and Ernzerhof ${ }^{19}$ (PBEO)] and ab initio [Hartree-Fock, (HF), Møller-Plesset second-order Perturbation theory, (MP2) approximation combined with large Guassian basis sets[6$311+G(d, p), 6-311++G(d, p)]$, methodologies used to obtain more accurate qualitative energetical results.
- HF method with medium basis set $6-31 \mathrm{G}(\mathrm{d})$ used to determine ionization potential according Koopman's theorem, since HF model fully neglecting the electron correlation effects correct the errors of single determinant due to ignoring relaxation of spin orbitals ${ }^{20}$.
- The pathway for intermolecular conversion from two conformation is employed to confirm the number of stationary points of Potential energy surface, the calculations are current with hybrid Beck method B3LYP/6-31G(d) and single point (sp) energy calculated for each 10 degrees.
- All calculations are carried out using Guassian03 ${ }^{21}$ quantum chemistry package.

## RESULTS AND DISCUSSION

Geometrical structure: A geometrical investigation has been carried by evolution pesoudorotation phase angle $P$, maximum amplitude of puckering $\nu_{\text {max }}$ and the three exocyclic rotation angles $\chi\left(\mathrm{O}^{\prime}-\mathrm{C}^{\prime}-\mathrm{N} 1-\mathrm{C} 2\right), \gamma\left(\mathrm{C}^{\prime}-\mathrm{C} 4{ }^{\prime}-\mathrm{C} 5{ }^{\prime}-\mathrm{O} 5 '\right), \beta(\mathrm{H} 5 '-$ O5'-C5'-C4'). Furanose ring is twisted out of plane in order to minimize non-bonded interactions between their substituents. Table- 1 shows P values of anti conformers local in range (72-

TABLE-1
PHASE ANGLE, MAXIMUM AMPLITUDE AND TO INTERNAL DIHEDRAL ANGLES $\gamma\left(\mathrm{O}^{\prime}-\mathrm{C} 5 '-\mathrm{C} 4^{\prime}-\mathrm{C} 3\right.$ '), $\chi(\mathrm{C} 2-\mathrm{N} 1-\mathrm{C} 1$ '-O1'), $\beta=$ (H5'-O5'-C5'-C4') OF PUCKERING VALUES IN (DEGREES) EVALUATED BY B3LYP/6-31G(d) LEVEL

108), in this case the sugar ring take O4'-endo, i.e., anti conformers form envelop configuration, in which all atoms of five sugar member ring lying in plane except $\mathrm{O}^{\prime}$ ' atom, which prefers to oppositional C5' side, while corresponding syn conformers, involving two phase angle modes, one is C2'-exo for D 4 T and the other, C 1 '-exo which is obtained by the reminding derivatives has C 1 '-exo mode. Among other compounds, the largest values of P angles are recorded for anti D 4 T and cyano-D4T conformers.

In other hand, the values of $v_{\text {max }}$ confirm this behavour. Their results showed irregular variation for the two conformers, the substitution cause increasing in puckering amplitude of five sugar member ring, which is syn conformers and the other shows $v_{\text {max }}$ values lower (methyl and allyl)-D4 $\mathrm{T}_{\mathrm{s}}$ and the larger (the reminding substituents ) than D4T.

The substitution of anti C4'-position by the different (except cyano) groups in D 4 T alters the sugar ring conformation from N to S , but that have not showed for syn conformer, the furanose rings have (S) type for all syn conformers. In general, vinyl substituted D4Ts show larger puckering than other compounds, in addition, the puckering in five sugar member ring of anti conformation molecules relatively larger than the corresponding syn, overall, the maximum amplitude of puckering is less than 20 , that is, the five sugar member ring considerably flat ${ }^{22}$.

## Energetics

Bond dissociation energy (BDE): Anti-conformation of this type of inhibitors are necessary for biological activity ${ }^{23}$ so we prefer to investigate about strength of C 1 '- X bond where the different groups link to five member ring of ribose. Table-2 lists bond dissociation energies (BDEs) of nucleosidegroup ( $\mathrm{C} 1{ }^{\prime}-\mathrm{X}$ ) bond for these different groups for anti conformation of D4T and it's derivatives, bond energies vary from model chemistry to another the DFT model different from each other as and each of PBE0 and B3LYP contrast to MP2. "The different approximate solutions to the Schrödinger equation often lead to different predictions. There is no reason why two approximations must give the same trends" ${ }^{24}$. However, all methods confirm that ( C 1 '-allyl) bond is weaker than the others.

Total and frontal energies: The total energy of two conformations and the difference explicit that syn conformation is suffering from more steric than anti conformers. In other word the anti conformation is energetically preferred than syn. This is due to bulky carbonyl group electronic cloud be close over the five sugar member ring. Of course, the correlation energy lower the electronic energies and that reflect on occupies energies, which are derivatives from electronic energy by population analysis, Table-3 agrees with this fact, Hartree common energies for all substituents of both conformations are significantly difference from other level theories, 9.4 eV and unoccupied orbitals in DFT tend to be significantly lower in energy than corresponding HF ones and the highest occupied molecular orbital-lowest unoccupied molecular orbital (HOMO-LUMO) gaps are therefore much smaller with DFT methods than for HF.

In general, KS occupied orbitals are higher than HF orbitals, while virtual KS orbitals are lower than HF orbitals. Therefore, HOMO-LUMO energy gap is larger in HF than in KS.

Ionization energies: Four different level theories are employed to determine Ionization energy according to the fact that negative of HOMOs is representing the energy need to remove their corresponding electrons. (Fig. 3) shows the vertical ionization potentials. HF is logically more give more accurate ionization energies due to two reasons; first because it result derivate for HF theory, the other, although, it is ignore the orbital relaxation, the correlation effect ignoring cancel that error, In general, it's clear that cyanide substituted compounds of two conformers are have higher ionization energy than other substituted compounds.

Rotational barrier energies: The activation energy of anti and syn conformer are obtained for rotation barrier (Table4), for convert syn conformation to anti $\Delta \mathrm{E} \# 1$ for path 1 and the corresponding process $\Delta \mathrm{E} \# 2$ when rotation about single bond is in other side passing over high density Oxygen five member ring atom, $\Delta \mathrm{E} \# 2$ so, more steric hindrance, so higher barrier value and barrier energy is similar for what is observed experimentally for pyrimidine nucleosides ${ }^{25}$.

## Surfaces

Potential energy surface (PES): The pathway for intermolecular conversion due to rotation about C 1 '-N1 is described in Figs. 4 and 5, its representation of potential energies surface of relative energy against external rotational angles, a potential curve for $6-31 \mathrm{G}(\mathrm{d})$ showing, the comparison of 4 -substitued

$\mathrm{a}=$ TS energy evaluated by B3LYP/6-31G(d). $\mathrm{b}=$ TS energy evaluated by high level theory B3LYP/6311++G(d,p) //RB3LYP/6-31G(d). $\mathrm{c}=$ difference between first transition state $\left(\mathrm{TS}^{a}\right)$ and total energy of Syn conformer. $\mathrm{d}=$ difference between first transition state $\left(\mathrm{TS}^{b}\right)$ and total energy of Syn conformer.

Fig. 5. One dimensional Potential energy surface scheme of $g$ dihedral angles E total relative energy, (O5'-C5'-C4'-C3')

D4T corresponding to unsubstituted one. the scheme show that anti conformer is energetically preferred rather than syn. In other hand, there is no significant change on $\chi$ angle by the substitution, but that effect had showed into $\gamma$ exocyclic rotation angle, D4T curve different from that of all others. All maxima except cyano-D4T, are shifted $20^{\circ}$ toward left side. In other words, the hinder of bulky group shows at range (80$100)^{\circ}$ rather than $(100-120)^{\circ}$ of D4T and cyano-D4T. This is not mean that the potential energy surface of D4T matching to cyano-D4T, the significant difference between the two molecules show after the maximum point of the curve, potential energy surface of D4T is smoother than the substituents behind $160^{\circ}$. Moreover, the allyl-D4T curve show four peaks different from all the other compounds which have three peaks, due to bulky non-symmetric allyl group.

It's important to plot effect of change of two rotation ( $\chi$, $\gamma$ ) angles simultaneously with relative energies for D4T schemed (Fig. 6). The important point should be noticed about this plot, is that drastically change happen in curve from maxima to minima from 60 to 80 and 340 to $360^{\circ}$, just when two angles has rotated by $20^{\circ}$ at both regions, 60 and 80 , hydrogen bonded. Moreover, the hydrogen bonding between oxygen of nitrogen base (O2) and carboxylic hydrogen H 5 ', of the maximum point geometry ( $1.711 \AA$ ) is closer than corresponding one at minimum ( $1.845 \AA$ ). but the large cloud of $\mathrm{O} 5^{\prime}$ atom is closer to minimum point geometry $\left(80^{\circ}\right)$ rather than maximum one.
$(\gamma: \chi)^{\circ}$

Electrostatic potential (EPS): Electrostatic potential representation are illustrated in (Fig. 3) for anti conformer. It's clear the red area represent the higher electron charge zone and the blue the electron deficient ones, most of negative charge concentrate on oxygen and nitrogen atoms in all molecules sincethere two atoms contain electron pairs. As well the hydrogen atoms that attached in oxygen and nitrogen is suffering from electron density deficiency. It clear that each Fig. 3a,3f, 3e compounds have electron density condense into triple bonds, which is (cyano, ethynyl and methylethynly)D4T whereas the relatively low electron density onto triple bond with chloroethynyl substituted compound Fig. 3h which is not appears bioactivity against NRTIs as well, the electrostatic potential not show the cyanostavudine electron density non-localized on tripe cyano group, due to electron pair on nitrogen atom.

## Conclusion

The results showed that there are four stationary points and one dimensional potential energy surface produced from pyrimidine ring rotation about glycosidic bond ( $\mathrm{N} 1-\mathrm{C} 1$ ') respect to five sugar ring. The five member ring will less puckering against different substituent, BODs show that allyl-substitution group is less stable that others. Five sugar member ring of anti conformer is more distortion from syn. All substituents in syn conformation cause increasing the puckering of sugar ring but that not true for anti, the five sugar member ring become more planar when the ally and methyl groups have entered.
